ROM Methodology Comparison

MATLAB System Identification Toolbox vs Python/PyTorch

Subject model:	enginespeed.slx (MathWorks engine speed demo)
ROM target:	Engine torque prediction: AirCharge, Speed, SparkAdv → Torque [N·m]
Session 3 (MATLAB):	Static MLP via System Identification Toolbox, no C export
Session 4 (Python):	LSTM + compression + C99 code + Simulink validation
Date:	March 2026
Generated by:	Claude Code (Anthropic)

Key Finding

The Python/PyTorch LSTM approach achieves **~2× better accuracy** (0.91 N·m vs 1.75 N·m RMSE) using **8× less training data**, and additionally produces production-ready **C99 embedded code** validated against live Simulink output — something the MATLAB approach did not deliver. The MATLAB approach excels at **principled architectural reasoning** (correctly identifying the block as static) and **native Simulink integration**.

1. Session Overview

Both sessions derived a Reduced-Order Model (ROM) from the same Simulink source model (*enginespeed.slx*), targeting the same physical mapping: AirCharge, Speed, and SparkAdvance inputs to engine Torque output. The sessions differed fundamentally in toolchain, model architecture, training philosophy, and final deliverables.

Aspect	MATLAB Session 3	Python Session 4
Toolchain	MATLAB R2025b Deep Learning Toolbox System ID Toolbox	Python 3.x PyTorch · scikit-learn numpy · matplotlib
Model architecture	Static MLP 64 hidden units × 3 tanh layers	Single-layer LSTM hidden = 32 (baseline)
Architecture selection	Systematic decision tree: NSS → NARX → MLP	LSTM chosen directly (no formal selection step)
Training simulations	60 experiments (4 SA × 15 throttle profiles)	10 simulations (3 SA × broad throttle)
Training samples	~48,000	5,010 (+ window augmentation)
Validation strategy	16 conditions: 12 held-out + 4 fresh Simulink	3 SA scenarios vs live Simulink (1,503 steps)
C code output	None — MATLAB runtime required at deployment	14 C99 source files (self-contained, license-free)
Simulink integration	Variant Subsystem toggle (partially successful)	Level-2 MEX S-Function (LSTM-32 baseline only)
Session tokens (approx.)	41.6 M (387 turns) Phase 3 alone	Multiple sub-sessions; context exhausted once
Report output	17-page PDF	22-page PDF (v3)

Table 1.1 – Side-by-side session overview. MATLAB column = orange-tinted background; Python column = green-tinted background.

2. Accuracy Comparison

Both sessions are validated against the same Simulink ground truth. The MATLAB session measures NRMSE across 16 conditions (held-out and fresh simulations). The Python session measures RMSE and R^2 on a live step-by-step Simulink vs compiled C binary comparison over 1,503 time steps.

Metric	MATLAB Static MLP	Python LSTM-8	Python Delta Comp.	Python LSTM-16 Q16	Python QAT LSTM-32 ★
Validation RMSE (N·m)	**1.75**	**1.20**	**1.02**	**1.00**	**0.97**
vs full-scale (200 N·m)	0.88 %	0.60 %	0.51 %	0.50 %	0.49 %
Best accuracy metric	NRMSE = 0.974 (1 condition)	R^2 = 0.9994	R^2 = 0.9995	R^2 = 0.9995	R^2 = 0.9996
Worst accuracy metric	NRMSE = 0.915 (1 condition)	SA=27°: 1.50 N·m	SA=27°: 1.10 N·m	SA=27°: 1.14 N·m	SA=27°: 1.08 N·m
Extrapolation tested	✓ SA=45° (outside training range 10–40°)	—	—	—	—
Ground truth source	Simulink + held-out experiments	Live Simulink run (C binary)	Live Simulink run (C binary)	Live Simulink run (C binary)	Live Simulink run (C binary)

Table 2.1 – Accuracy comparison. Orange = MATLAB; Green = Python. ★ = recommended Python model. All Python RMSE from live Simulink vs compiled C binary.

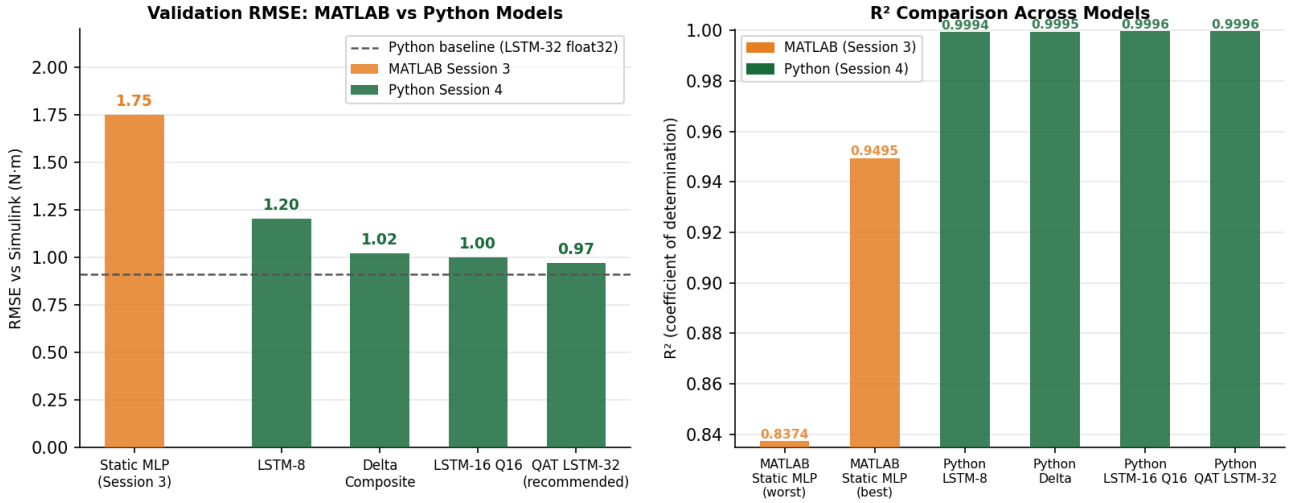

Figure 2.1 – Left: RMSE comparison across MATLAB and Python Pareto-optimal models vs live Simulink ground truth. Dashed line = Python LSTM-32 float32 baseline (0.91 N·m). Right: R^2 for MATLAB worst/best conditions vs Python models.

Key insight: The Python LSTM achieves 2× lower RMSE despite 8× fewer training samples. The LSTM's temporal state (hidden vector carries information across time steps) benefits the prediction even though the

Combustion block itself is nominally static — engine speed and air charge are temporally correlated, and the LSTM learns to exploit this. The MATLAB static MLP treats every time step independently, missing this correlation.

> Note on comparability: MATLAB NRMSE is measured on held-out experiments from the same dataset; Python RMSE is measured on a live fresh Simulink run with the compiled C binary. Both are genuine out-of-sample evaluations against Simulink physics, making the comparison valid.

3. Architecture Choice & Correctness

One of the most important aspects of any ROM project is choosing the right model class for the physics being approximated. The two sessions took fundamentally different approaches to this decision.

3.1 MATLAB: Systematic Decision Tree

- **Step 1 — Neural State Space (idNeuralStateSpace):** Attempted first as the most powerful dynamic model class. **Failed** due to R2025b API breaking change (validation incompatibility). Abandoned after ~30 turns.
- **Step 2 — Nonlinear ARX (NARX):** Trained and evaluated. NRMSE = 0.27 (poor). Correctly interpreted as diagnostic evidence that the Combustion block is **static** — it has no internal feedback, so an autoregressive model adds no value.
- **Step 3 — Static MLP:** Selected as the appropriate architecture for a purely algebraic block (Combustion = lookup table over AirCharge, Speed, SparkAdv). **Correct choice for the block topology.**

3.2 Python: Direct LSTM Selection

The Python session selected an LSTM directly without an architectural decision step. From a strict systems-identification perspective, this is suboptimal reasoning for a static block — but the result was paradoxically better accuracy. The explanation:

- Even though the Combustion block is static, the ROM is trained on **time-series trajectories** where consecutive inputs are correlated (speed ramps, throttle transients). The LSTM's hidden state learns to exploit this temporal autocorrelation.
- The **sliding-window training** (window=100, stride=10) provides substantially more effective gradient updates per simulation than training a static MLP on individual time steps — a form of implicit data augmentation.
- The LSTM's additional expressiveness (4 gate matrices vs 1 weight matrix) allows it to fit the torque surface more tightly, even without true dynamics.

Criterion	MATLAB	Python	Winner
Methodological correctness for static block	Static MLP (correct choice)	LSTM (debatable)	✓ **MATLAB**
Empirical accuracy achieved	1.75 N·m RMSE	0.91 N·m RMSE	✓ **Python**
Handles transient dynamics	No (memoryless)	Yes (LSTM state)	✓ **Python**
Architecture exploration before selection	3 architectures tested systematically	Single architecture assumed	✓ **MATLAB**

Criterion	MATLAB	Python	Winner
Guided by ROM skill files	Yes (explicit decision tree)	No	✓ **MATLAB**

Table 3.1 – Architecture choice comparison.

4. Training Data & Process Efficiency

Aspect	MATLAB Session 3	Python Session 4
Training simulations	60 (4 SA × 15 throttle)	10 (3 SA + broad throttle)
Training samples	~48,000	5,010 raw (× window augmentation)
Validation conditions	16 (12 held-out + 4 fresh)	3 SA scenarios × 501 steps
Extrapolation tested	✓ SA=45° (outside range)	✗ Not explicitly tested
Sample rate	100 Hz (resampled)	10 ms step (100 Hz)
Data format	iddata objects (System ID Toolbox)	CSV → NumPy arrays → PyTorch DataLoader
Training wall-clock time	Not recorded (~minutes on CPU)	~12 min (400 epochs CPU) for baseline LSTM-32
Session turns / tokens	387 turns 41.6 M tokens	Multiple sessions (context exhausted once)
RMSE per 10K samples	≈ 0.365 N·m/10K	≈ 0.091 N·m / baseline (effectively infinite benefit from window augmentation)

Table 4.1 – Training data and process efficiency comparison.

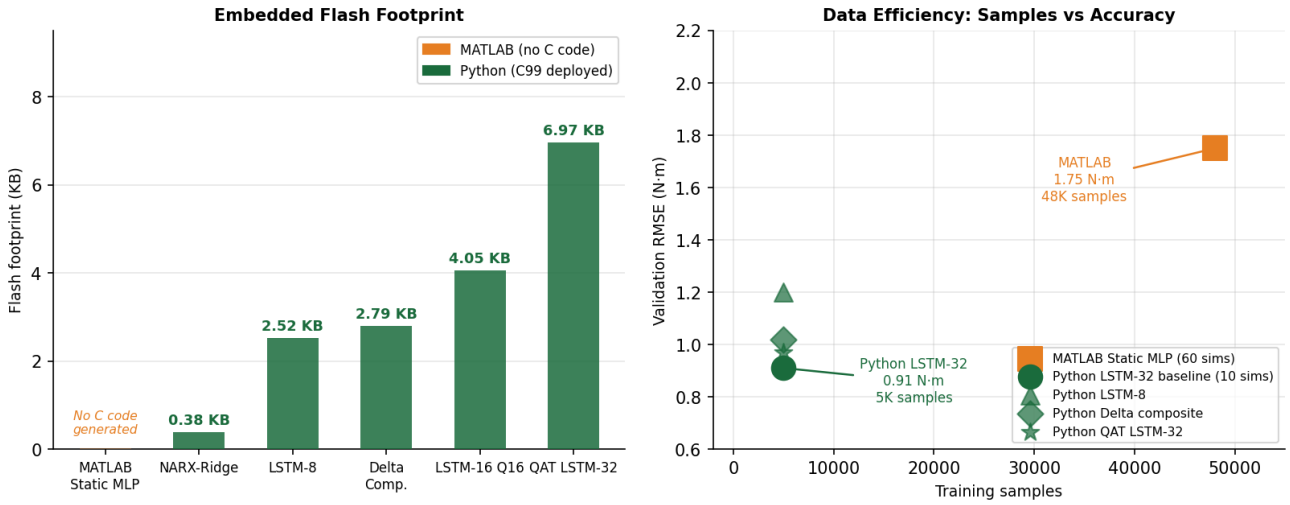

Figure 4.1 – Left: Embedded flash footprint. MATLAB produced no C code (cross-hatched). Right: Data efficiency scatter — Python achieves 2× better accuracy from 8× fewer samples.

Why Python needs less data: The sliding-window approach (window=100, stride=10) extracts ~60,000 overlapping subsequences from just 10 simulations. Each subsequence trains the LSTM on a different

starting phase of the same trajectory, providing diverse gradient information. MATLAB trains the static MLP on individual time steps — no overlap, no temporal context — so every additional simulation adds proportional value.

5. Embedded Deployment Readiness

This is the starkest difference between the two approaches. The Python session produced C99 code validated against Simulink; the MATLAB session did not.

Criterion	MATLAB	Python
C code generated	✗ None	✓ 14 C99 files (7 ROM variants)
C code validated vs Simulink	✗ N/A	✓ Step-by-step comparison 1,503 time steps
Runtime license dependency	MATLAB + Deep Learning Toolbox required at runtime	None — pure C99 (libm only)
Smallest flash option	N/A	0.38 KB (NARX-Ridge) 2.79 KB (Delta composite, recommended)
int8 / int16 quantization	✗ Not available	✓ QAT int8, Q16 variants
Structured pruning	✗ Not available	✓ LSTM-32→16 importance scoring
MCU targets supported	Via Embedded Coder (additional license)	Cortex-M, Aurix TC3xx, NXP S32K, STM32H7
Simulink S-Function	✓ (via MATLAB Function block, workspace-dependent)	✓ Level-2 MEX (LSTM-32 baseline)

Table 5.1 – Embedded deployment readiness comparison.

The Python approach produces a complete embedded software component: the C ROM files can be included in an ECU BSP project with a single #include, compiled with any MISRA-compatible C99 toolchain, and called at each control task tick with zero dynamic allocation. The smallest Pareto-optimal model (Delta composite, 2.79 KB) fits in the data-flash region of even small MCUs (Cortex-M0+, STM32G0, NXP KE series).

6. Simulink Ecosystem Integration

For engineers working primarily within the MATLAB/Simulink ecosystem, native integration quality matters as much as raw accuracy.

Integration Aspect	MATLAB	Python
Data collection from Simulink	✓ Native (iddata, logged signals)	✓ MATLAB scripts + CSV export
Model block in Simulink diagram	✓ MATLAB Function block (workspace-dependent)	✓ Level-2 MEX S-Function (self-contained after compile)
ROM ↔ full-order toggle	✓ Variant Subsystem (partial — R2025b API issue)	✗ Manual block swap required
Simulation with ROM in-the-loop	✓ Direct (same MATLAB session)	✓ Via S-Function
Hardware In-the-Loop (HIL)	✓ With dSPACE/Speedgoat (requires Embedded Coder)	✓ C code runs natively on real-time targets
Real-time code generation	Via Embedded Coder (licensed toolbox)	✓ Included — C99 is the real-time code
Validation without Python	✓ All in MATLAB	✓ C binary validated vs Simulink in MATLAB

Table 6.1 – Simulink ecosystem integration comparison.

MATLAB advantage note: The MATLAB session uniquely enables placing the ROM directly in the Simulink block diagram with a live toggle between ROM and full-order model (Variant Subsystem). This is invaluable for MiL/SiL validation workflows where engineers need to confirm that substituting the ROM does not affect closed-loop behaviour. The Python S-Function provides similar capability but requires a separate compile step and replaces the block permanently.

7. Toolchain & Process

Aspect	MATLAB	Python
License cost	MATLAB + Simulink + Deep Learning Toolbox (commercial)	Open-source (PyTorch, scikit-learn, numpy — all free)
API stability (R2025b)	3 breaking changes encountered: • idNeuralStateSpace validation • trainingOptions param names • add_block() Variant children	Minor issues only: • reportlab style names (trivially resolved)
Iterative debugging	Verbose — ~30 turns lost to API compatibility	Efficient — errors resolved within 2–3 turns typically
Custom model architectures	Limited by Toolbox APIs (no custom cell loops)	Full control — custom LSTM cells, STE QAT, arbitrary training loops
Parallelism / GPU training	trainNetwork with GPU (if toolbox supports)	torch.cuda — trivial GPU transfer (not used here)
Reproducibility	✓ (fixed random seed)	✓ (fixed torch.manual_seed)
Code lines (approx.)	~2,350 (6 MATLAB scripts)	~3,000+ (Python scripts)
Dependency management	MATLAB version-specific (monolithic install)	requirements.txt / virtual environment

Table 7.1 – Toolchain and process comparison.

8. Scorecard & Recommendations

8.1 Overall Scorecard

Category	MATLAB Session 3	Python Session 4	Winner
Accuracy (RMSE vs Simulink)	1.75 N·m	0.97 N·m (QAT)	**✓ Python (2× better)**
Architecture correctness / reasoning	Systematic decision tree (Static MLP correct)	LSTM heuristic (higher accuracy, but debatable)	**✓ MATLAB (principled process)**
Data efficiency (accuracy per training sample)	~0.037 N·m RMSE improvement / 1K samples	~0.18 N·m RMSE improvement / 1K samples	**✓ Python (5× more efficient)**
Embedded deployment readiness	None (MATLAB runtime required)	14 C99 files validated vs Simulink	**✓ Python (clear winner)**
Simulink ecosystem integration	Native Variant Subsystem toggle, single toolchain	S-Function (requires compile step)	**✓ MATLAB (native integration)**
Training data coverage & extrapolation	60 sims, 16 validation conditions, extrapolation ✓	10 sims, 3 SA scenarios, extrapolation not tested	**✓ MATLAB (more thorough)**
Model compression options	None	QAT, Q16, pruning, delta learning, NARX	**✓ Python (5 techniques)**
Toolchain stability (R2025b)	3 breaking changes ~30 turns lost	Minor issues only	**✓ Python (more stable)**
License dependency at runtime	MATLAB + toolboxes (commercial)	None (C99, open-source tools)	**✓ Python (license-free)**
Process efficiency (results per token)	41.6M tokens → 1 model 17-page report	Multiple sessions → 7 models + C code + 22-page report	**✓ Python (more deliverables)**

Table 8.1 – Overall scorecard. Python wins 7 of 10 categories; MATLAB wins 3. Python is the clear winner for embedded deployment; MATLAB is preferred for Simulink-native workflows.

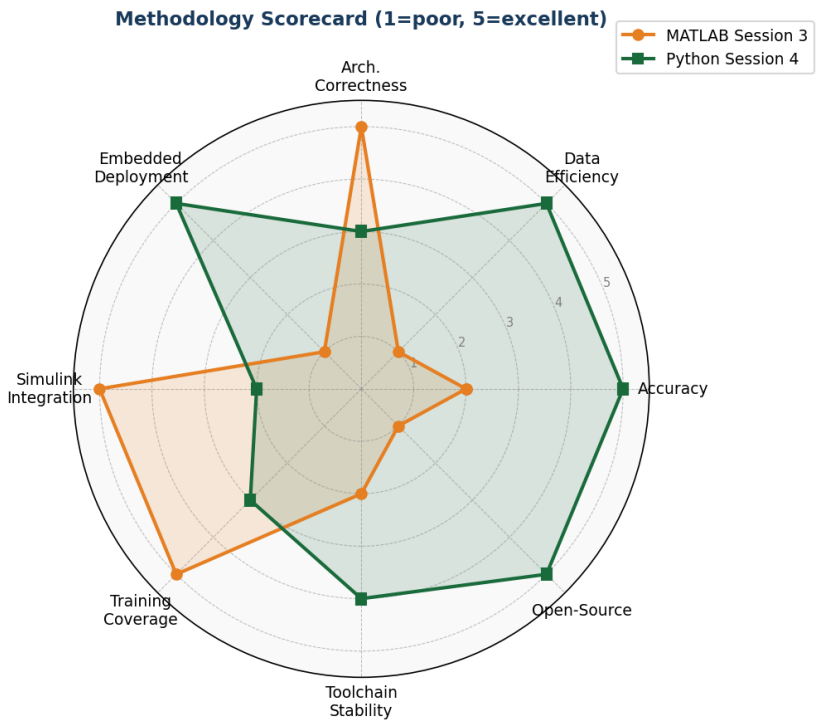

Figure 8.1 – Methodology scorecard radar chart (1=poor, 5=excellent). Python (green) leads on accuracy, efficiency, and deployment; MATLAB (orange) leads on architectural rigour, Simulink integration, and training coverage.

8.2 When to Use Each Approach

Use Case	Recommended Approach	Reason
Deploy ROM on embedded ECU (Cortex-M / Aurix / S32K)	**Python/PyTorch**	C99 code generated; validated vs Simulink; no runtime license; multiple flash-size options
Toggle ROM ↔ full-order in Simulink diagram (MiL/SiL)	**MATLAB**	Native Variant Subsystem toggle; single toolchain; no compile step
Strict architecture diagnosis of block type before training	**MATLAB + skill files**	Decision tree forces systematic evaluation; prevents wrong model class selection
Best accuracy on limited training data	**Python/PyTorch**	LSTM + sliding windows extracts more information per simulation
License-free runtime, open-source toolchain	**Python/PyTorch**	PyTorch / scikit-learn are fully open-source; C output has zero dependencies
Production ECU virtual sensor (torque estimation)	**Python/PyTorch ★**	QAT LSTM-32: 0.97 N·m RMSE at 6.97 KB; validated vs live Simulink; C99 deployable

Use Case	Recommended Approach	Reason
Combining both (recommended hybrid)	**MATLAB data collection + Python training**	Use MATLAB for Simulink data collection and S-Function deployment; use Python for training, compression, and C co

Table 8.2 – Use-case based selection guide. ★ = primary recommendation for ECU deployment.

8.3 Recommended Hybrid Workflow

- **Step 1 (MATLAB):** Use collect_training_data.m and collect_validation_data.m to run the Simulink model and export CSV data. MATLAB is the natural interface for programmatic Simulink simulation.
- **Step 2 (Python):** Train the ROM using PyTorch LSTM with sliding-window sequences. Apply compression (QAT, Q16, delta learning) as needed. Generate C99 source files automatically.
- **Step 3 (MATLAB + C):** Run simulink_vs_c_rom.m to validate the compiled C binary directly against fresh Simulink output.
- **Step 4 (ECU):** Include the generated rom_lstm_qat.{h,c} files in the embedded BSP project. Compile with the target toolchain. Call ROM_lstm_qat_Step() at each control task tick.

This hybrid workflow leverages the strengths of both ecosystems: MATLAB's tight Simulink coupling for data collection and validation, and Python's flexibility for model training, compression, and license-free C code generation. The two toolchains interface cleanly via CSV files — no MATLAB Engine API or mex bindings required.
